Strain rate vs. Tissue Doppler

Doppler Feature "Speckle" Tracking

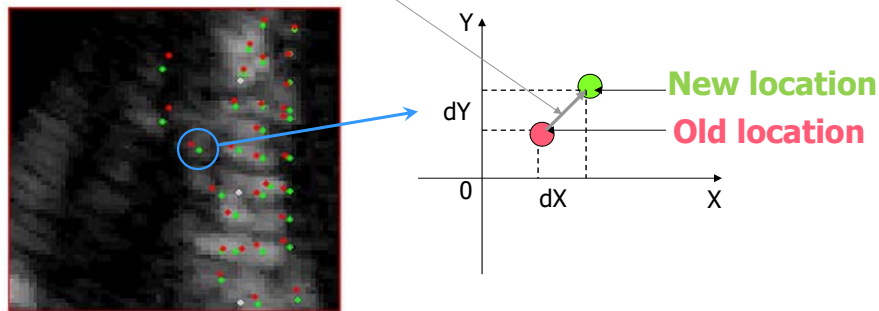

Movement of the myocardium relative to the sample volume fixed in space

Acoustic pattern tracking Speckle Tracking

Velocity is estimated as a shift of each object divided by time between successive frames (or multiplied by Frame Rate)-->

2D vector: $(V_x, V_y) = (dX, dY) * FR$

Doppler Independent Techniques (Speckle Tracking)

Potential Advantage?

- Signal noise
- Speckle tracking by principle is angle independent
- Gray scale (standard views)
- Monitor strain in two rather than one dimension
- Minimal user input
- Assessment of rotation: derived from circumferential strain at different levels in the heart (**NO fixed sample volume**)

Echocardiographic Measures of Myocardial Deformation by Speckle-Tracking Technologies: The Need for Standardization?

Matthew R. Nelson, MD, R. Todd Hurst, MD, Serageldin F. Raslan, MD, Stephen Cha, MS, Susan Wilansky, MD, and Steven J. Lester, MD, *Scottsdale, Arizona; Rochester, Minnesota*

Echocardiographic Measures of Myocardial Deformation by Speckle-Tracking Technologies: The Need for Standardization?

than two left ventricular endocardial segments poorly delineated were excluded. GLS was obtained from the apical four-chamber, three-chamber, and two-chamber views using two independent speckle-tracking echocardiographic software packages (EchoInsight version 1.5.0 and Image-Arena version 4.5). Linear regression analysis and paired *t* tests were used to compare GLS results. Intraclass correlation coefficients and Bland-Altman plots were used for assessments of reliability.

Results: The "out-of-the-box" mean GLS was $-12.99 \pm 2.38\%$ using EchoInsight and $-16.87 \pm 2.84\%$ using Image-Arena (mean difference, $3.87 \pm 2.42\%$; $P = .0001$). Agreement between the software packages was moderate (intraclass correlation coefficient, 0.43; 95% confidence interval, 0.32-0.55). Using uniform variables to derive GLS (i.e., apical strain measured in systole and diastole at the endocardium and averaging the peak segmental strain) improved agreement between the two packages (mean difference, $0.52 \pm 0.79\%$).

J Am Soc Echocardiogr 2012;25:1189-94

Conclusions: Image-Arena GLS results were consistently different (more negative) than EchoInsight measures out of the box but became similar when information used to derive GLS was uniform. The evolution of measures of myocardial mechanics into routine clinical practice will require vigilance and standardization of the various techniques, necessitating independent validation of commercially available speckle-tracking echocardiographic products. (J Am Soc Echocardiogr 2012;25:1189-94.)

REPRODUCIBILITY OF LEFT VENTRICULAR STRAIN

Head-to-Head Comparison of Global Longitudinal Strain Measurements among Nine Different Vendors The EACVI/ASE Inter-Vendor Comparison Study

Konstantinos E. Farsalinos, MD, Ana M. Daraban, MD, Serkan Ünlü, MD, James D. Thomas, MD, Luigi P. Badano, MD, PhD, and Jens-Uwe Voigt, MD, PhD, *Leuven, Belgium; Chicago, Illinois; and Padua, Italy*

Background: This study was planned by the EACVI/ASE/Industry Task Force to Standardize Deformation Imaging to (1) test the variability of speckle-tracking global longitudinal strain (GLS) measurements among different vendors and (2) compare GLS measurement variability with conventional echocardiographic parameters.

Methods: Sixty-two volunteers were studied using ultrasound systems from seven manufacturers. Each volunteer was examined by the same sonographer on all machines. Inter- and intraobserver variability was determined in a true test-retest setting. Conventional echocardiographic parameters were acquired for comparison. Using the software packages of the respective manufacturer and of two software-only vendors, endocardial GLS was measured because it was the only GLS parameter that could be provided by all manufacturers. We compared GLS_{AV} (the average from the three apical views) and GLS_{4CH} (measured in the four-chamber view) measurements among vendors and with the conventional echocardiographic parameters.

Results: Absolute values of GLS_{AV} ranged from 18.0% to 21.5%, while GLS_{4CH} ranged from 17.9% to 21.4%. The absolute difference between vendors for GLS_{AV} was up to 3.7% strain units ($P < .001$). The interobserver relative mean errors were 5.4% to 8.6% for GLS_{AV} and 6.2% to 11.0% for GLS_{4CH}, while the intraobserver relative mean errors were 4.9% to 7.3% and 7.2% to 11.3%, respectively. These errors were lower than for left ventricular ejection fraction and most other conventional echocardiographic parameters.

Conclusion: Reproducibility of GLS measurements was good and in many cases superior to conventional echocardiographic measurements. The small but statistically significant variation among vendors should be considered in performing serial studies and reflects a reference point for ongoing standardization efforts. (J Am Soc Echocardiogr 2015;28:1171-81.)

GUIDELINES AND STANDARDS

Recommendations for Cardiac Chamber

Global Longitudinal Peak Systolic Strain (GLS)
“in the range of -20%”

are: Roberto M. L and MD FASE et al

- “Optimize image quality, maximize frame rate and minimize foreshortening”.
- “When regional tracking is suboptimal in more than two myocardial segments in a single view the calculation of GLS should be avoided”.

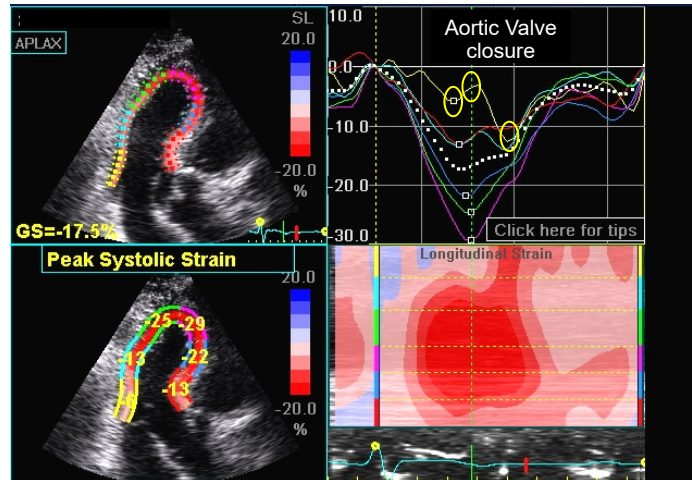

Every physician who performs echocardiography should be familiar with the guidelines and standards assembled by the American Society of Echocardiography and the European Association of Cardiovascular Imaging. This document provides updated normal values for all four cardiac chambers, including three-dimensional echocardiography and myocardial deformation, when possible, on the basis of considerably larger numbers of normal subjects, compiled from multiple databases. In addition, this document attempts to eliminate several minor discrepancies that existed between previously published guidelines. (J Am Soc Echocardiogr 2015;28:1-39.)

“Our data suggest that the temporal variability in EF of **0.06** might occur with noncontrast 3DE due to physiological differences and measurement variability, whereas this might be **>0.10** with 2D methods. Overall, 3DE also had the best intra- and inter-observer as well as test-retest variability”

Results

Among 56 patients (all female, 54 ± 13 years of age), noncontrast 3D EF, end-diastolic volume, and end-systolic volume had significantly lower temporal variability of LV end-diastolic volume and EF compared with 2D methods.

Inter-observer as well as test-retest variability.

Conclusions

Noncontrast 3DE was the most reproducible technique for LVEF and LV volume measurements over 1 year of follow-up. [J Am Coll Cardiol 2013;61:77-84] © 2013 by the American College of Cardiology Foundation

LV Mechanics in Mitral and Aortic Valve Diseases

Value of Functional Assessment Beyond Ejection Fraction

Elena Galli, MD, PhD,* Patrizio Lancellotti, MD, PhD,† Partho P. Sengupta, MD, DM,‡ Erwan Donal, MD, PhD*

ABSTRACT

- “LV dysfunction is frequently subclinical despite a normal ejection fraction. It may precede the onset of symptoms and portend a poor outcome...”
- “The advent of novel tissue-tracking echo techniques has unleashed new opportunities for the clinical identification of early abnormalities in LV function”.

regarding the use of these techniques to assess myocardial deformation in patients with valvular heart disease. (J Am Coll Cardiol Img 2014;7:1151-66) © 2014 by the American College of Cardiology Foundation.
